

RADIOGRAPHS/ X-RAYS

The use of X-rays in dentistry is considered a necessary component of a thorough dental examination. Many diseases of the mouth cannot be seen with the naked eye. If X-rays are not used, small cavities between the teeth, abscesses, cysts, tumors, and other diseases may be impossible to detect until obvious signs and symptoms have developed and the progression of oral disease is quite severe. Finding and treating dental problems at an early stage can save time, cost, and discomfort. If you have a hidden tumor, early diagnostic X-rays may even help save your life.

Problems cannot be treated without first being diagnosed. One of the most valuable diagnostic tools ever developed in medicine is the X-ray machine. By using X-rays carefully and prudently, we can offer our patients the excellent care they deserve.

What About Radiation Damage?

Scientists have known for some time that exposure to large amounts of radiation can be harmful to your body. With the modern techniques and equipment used in dental offices today, the amount of radiation received in a routine dental examination is extremely small. Therefore, the risk of harmful effects from dental X-rays is negligible.

We are exposed to natural background radiation daily from the Earth, sun, moon, and stars. It has been estimated that the average person receives about 300 millirem of radiation every year from the natural environment. By comparison, the four bitewing X-rays we recommend most patients have once a year deliver only 2 millirems of radiation.

How We Limit Your Radiation Exposure

There are many precautions we follow to help limit your child's radiation exposure:

- A lead shield, impenetrable by X-rays, covers your child's body.
- High speed film is used, so that the picture can be exposed with the smallest amount of X-ray dosage possible.
- The X-ray tube is designed to filter out and restrict the size of the X-ray beam.
- Employees wear radiation monitoring badges to detect radiation exposure. This process can help identify possible leaks in all the X-ray equipment. We have never had a report indicating unacceptable radiation levels.
- The KY Cabinet for Health and Family Services - Department of Radiation Health tests our X-ray equipment annually to assure safety for staff and patients.
- Routine, diagnostic bite-wing X-rays are taken on the back molars only, where the possibility of decay between the teeth is more likely.
